PROTOTYPE RESCUE

The demo was the easy part.

You've spent money and it fell over on real data. You know exactly what hurts. This is production-readiness triage — no code upload, no repo scan up front, just a conversation about what's actually broken.

01 **Auth**
Real sessions, not a client-side flag. Password reset that can't be used to take over an account.

02 **Secrets**
Nothing in the client bundle, nothing in the repo history, nothing in a public bucket.

03 **Error states**
What the user sees when the network drops, the API 500s, or the payment fails mid-flow.

04 **Rate limits**
What stops one script from taking down the app, or running up the AI bill.

05 **Data integrity**
Idempotency on writes, constraints that actually constrain, backups that have been restored at least once.

06 **Observability**
Whether anyone finds out before the customer does.

07 **Behaviour at 100× volume**
What breaks first when ten users becomes a thousand, and whether it fails loud or fails quiet.

FOR AI BUILDS — THE FIVE-ITEM SET

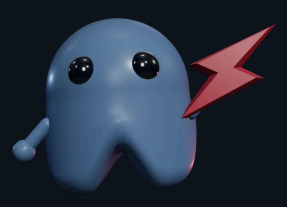

Evals
The line between a demo and a product.

Prompt versioning
What happens to behaviour when a prompt changes.

Human handoff
The escalation path when the model shouldn't answer.

Cost at volume
Modelled at real traffic, not demo traffic.

Grounding & containment
What it does when it's wrong in front of a customer.
